

# **Lecture-16**

By

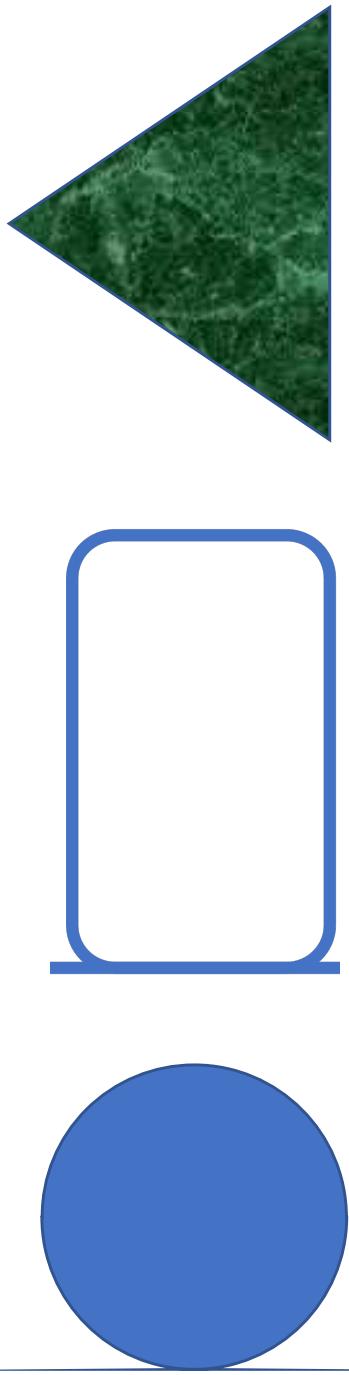

**Dr. Bharati Mishra**

# Objectives

- Chapter 11
  - Inheritance
    - Subclass, superclass
    - **super** keyword
    - **abstract** keyword
    - Overriding methods
    - Polymorphism and dynamic binding
    - **final** keyword
  - **ArrayList**

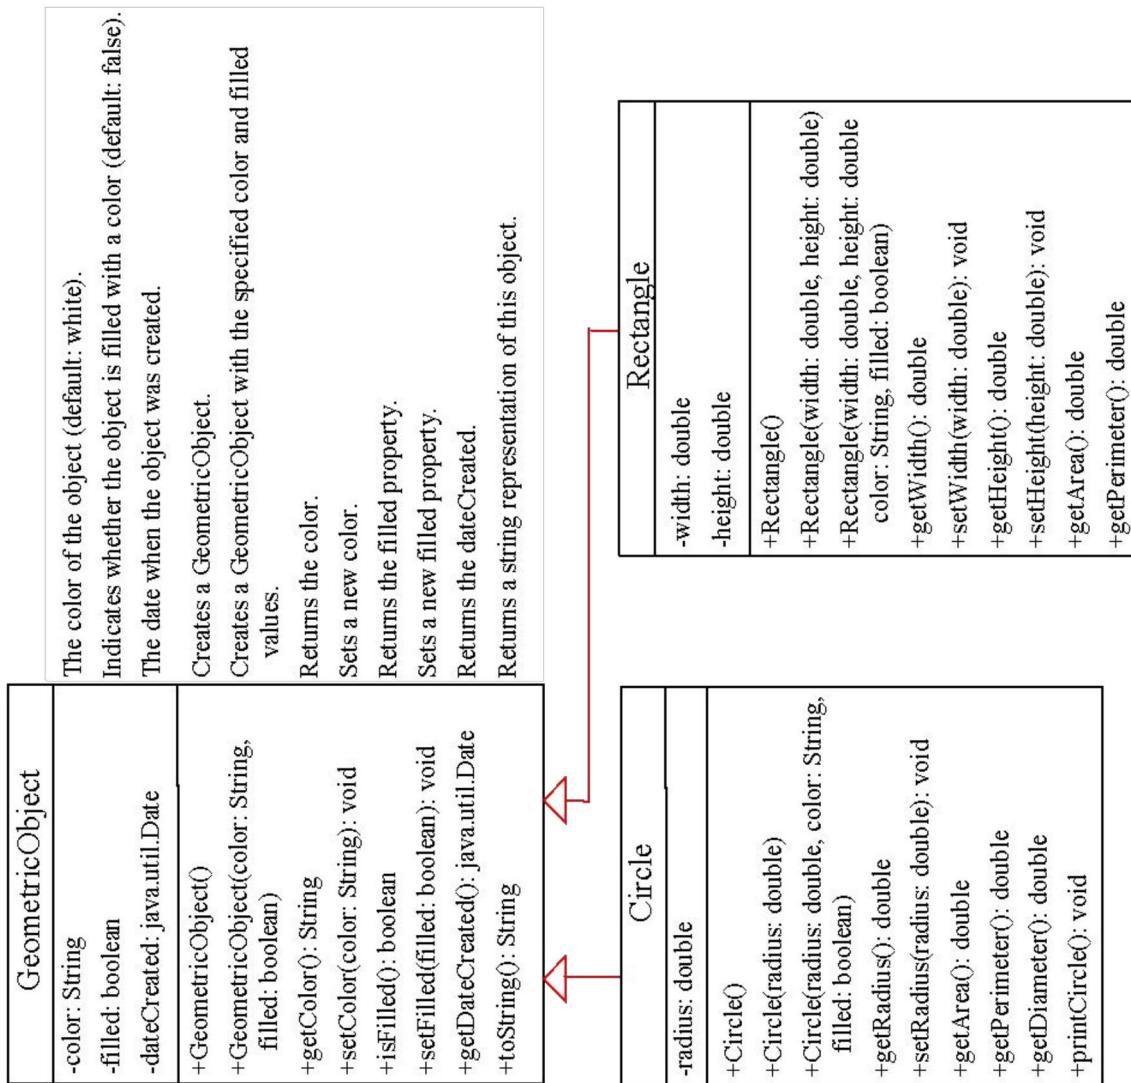

# Motivation

- Suppose you want to define classes to model circles, rectangles, and triangles.
- These classes have many common features.
- What is the best way to design these classes so to avoid redundancy?
  - The answer is to use inheritance.

# Inheritance

# Superclass

# Inheritance

- Models “is-a” relationship
- Not all “is-a” relationships should be modeled using inheritance
  - For class **A** to extend class **B**, **A** should contain more detailed information than **B**.
  - Do not blindly extend a class just for the sake of reusing methods!

# Inheritance

- A subclass does not inherit the private members of its parent class.
- A subclass is not a subset of the superclass
  - Contains more information!
- Java does not support multiple inheritance
  - It can be achieved through interfaces (an advanced topic)

# abstract

- An *abstract class* may or may not include abstract methods.
- Abstract classes cannot be instantiated, but they can be sub-classed.
- An *abstract method* is a method that is declared without an implementation.
- If a class includes abstract methods, the class itself *must* be declared abstract

# abstract

- An *abstract class* example

```
public abstract class GraphicObject
{
    // declare fields
    // declare non-abstract methods
    abstract void draw();
}
```

# Inheritance & Constructor

# Constructors

- Are superclass constructors inherited?
  - No. Unlike properties and methods, a superclass's constructors are not inherited in the subclass.

# Constructors

1. The constructors are invoked either explicitly:
  - Using the **super** keyword
2. Or implicitly:
  - If the keyword **super** is not explicitly used, the superclass's no-arg constructor is automatically invoked.

# Constructors

- A constructor may invoke
  - An overloaded constructor or
  - Its superclass's constructor
- If none of them is invoked explicitly, the compiler puts `super()` as the first statement in the constructor.

# Constructors

- Example

```
public ClassName() {  
    // some statements  
}
```

Equivalent

---

---

```
public ClassName() {  
    super();  
    // some statements  
}
```

```
public ClassName(double d) {  
    // some statements  
}
```

Equivalent

---

---

```
public ClassName(double d) {  
    super();  
    // some statements  
}
```

# super

- The keyword **super** refers to the superclass of the class in which **super** appears.
- This keyword can be used in two ways:
  - To call a superclass constructor
  - To call a superclass method

# Constructors

- You must use the keyword **super** to call the superclass constructor.
- Invoking a superclass constructor's name in a subclass causes a syntax error.
- Java requires that the statement that uses the keyword **super** appear first in the constructor.

# Chaining

- Constructor chaining

- Constructing an instance of a class invokes all the superclasses' constructors along the inheritance chain.
- This is called *constructor chaining*.

# Chaining

```
public class Faculty extends Employee {
    public static void main(String[] args) {
        new Faculty();
    }

    public Faculty() {
        System.out.println("(4) Performs Faculty's tasks");
    }
}

class Employee extends Person {
    public Employee() {
        this("(2) Invoke Employee's overloaded constructor");
        System.out.println("(3) Performs Employee's tasks");
    }

    public Employee(String s) {
        System.out.println(s);
    }
}

class Person {
    public Person() {
        System.out.println("(1) Performs Person's tasks");
    }
}
```

# Chaining

```
public class Faculty extends Employee {  
    public static void main(String[] args) {  
        new Faculty();  
  
        public Faculty() {  
            System.out.println(" (4) Faculty's no-arg constructor is invoked" );  
        }  
  
        class Employee extends Person {  
            public Employee() {  
                this(" (2) Invoke Employee's overloaded constructor" );  
                System.out.println(" (3) Employee's no-arg constructor is invoked" );  
            }  
  
            public Employee(String s) {  
                System.out.println(s);  
            }  
        }  
  
        class Person {  
            public Person() {  
                System.out.println(" (1) Person's no-arg constructor invoked" );  
            }  
        }  
    }  
}
```

1. Start from the main method

# Chaining

```
public class Faculty extends Employee {  
    public static void main(String[] args) {  
        new Faculty();  
    }  
  
    public Faculty() {  
        System.out.println(" (4) Faculty's no-arg constructor is invoked" );  
    }  
  
}  
  
class Employee extends Person {  
    public Employee() {  
        this(" (2) Invoke Employee's overloaded constructor" );  
        System.out.println(" (3) Employee's no-arg constructor is invoked" );  
    }  
  
    public Employee(String s) {  
        System.out.println(s);  
    }  
  
}  
  
class Person {  
    public Person() {  
        System.out.println(" (1) Person's no-arg constructor invoked" );  
    }  
}
```

**2. Invoke Faculty constructor**

# Chaining

```
public class Faculty extends Employee {  
    public static void main(String[] args) {  
        new Faculty();  
    }  
  
    public Faculty() {  
        System.out.println(" (4) Faculty's no-arg constructor is invoked" );  
    }  
  
    class Employee extends Person {  
        public Employee() {  
            this(" (2) Invoke Employee's overloaded constructor");  
        }  
        System.out.println(" (3) Employee's no-arg constructor is invoked" );  
    }  
  
    public Employee(String s) {  
        System.out.println(s);  
    }  
  
    class Person {  
        public Person() {  
            System.out.println(" (1) Person's no-arg constructor invoked" );  
        }  
    }  
}
```

3. Invoke Employee's  
no-arg constructor

# Chaining

```
public class Faculty extends Employee {  
    public static void main(String[] args) {  
        new Faculty();  
    }  
  
    public Faculty() {  
        System.out.println(" (4) Faculty's no-arg constructor is invoked" );  
    }  
  
    class Employee extends Person {  
        public Employee() {  
            this(" (2) Invoke Employee's overloaded constructor");  
            System.out.println(" (3) Employee's no-arg constructor is invoked" );  
        }  
  
        public Employee(String s) {  
            System.out.println(s);  
        }  
    }  
  
    class Person {  
        public Person() {  
            System.out.println(" (1) Person's no-arg constructor invoked" );  
        }  
    }  
}
```

4. Invoke  
Employee(String)

# Chaining

```
public class Faculty extends Employee {  
    public static void main(String[] args) {  
        new Faculty();  
    }  
  
    public Faculty() {  
        System.out.println(" (4) Faculty's no-arg constructor is invoked" );  
    }  
  
    class Employee extends Person {  
        public Employee() {  
            this(" (2) Invoke Employee's overloaded constructor");  
            System.out.println(" (3) Employee's no-arg constructor is invoked" );  
        }  
  
        public Employee(String s) {  
            System.out.println(s);  
        }  
    }  
  
    class Person {  
        public Person() {  
            System.out.println(" (1) Person's no-arg constructor invoked" );  
        }  
    }  
}
```

5. Invoke Person()  
constructor

# Chaining

```
public class Faculty extends Employee {  
    public static void main(String[] args) {  
        new Faculty();  
  
        public Faculty() {  
            System.out.println(" (4) Faculty's no-arg constructor is invoked" );  
        }  
  
        class Employee extends Person {  
            public Employee() {  
                this(" (2) Invoke Employee's overloaded constructor");  
                System.out.println(" (3) Employee's no-arg constructor is invoked" );  
            }  
  
            public Employee(String s) {  
                System.out.println(s);  
            }  
        }  
  
        class Person {  
            public Person() {  
                System.out.println(" (1) Person's no-arg constructor is invoked" );  
            }  
        }  
    }  
}
```

6. Execute println

# Chaining

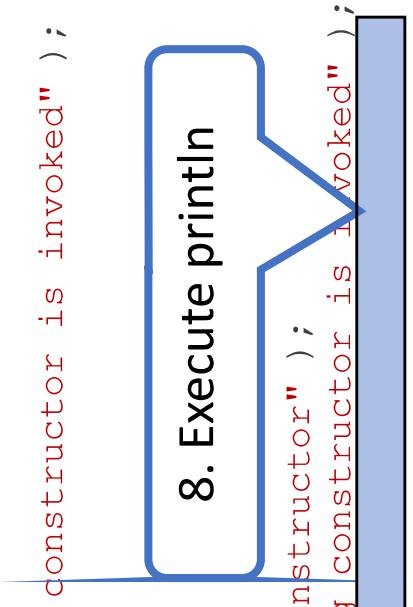

```
public class Faculty extends Employee {  
    public static void main(String[] args) {  
        new Faculty();  
  
        public Faculty() {  
            System.out.println(" (4) Faculty's no-arg constructor is invoked" );  
        }  
  
        class Employee extends Person {  
            public Employee() {  
                this(" (2) Invoke Employee's overloaded constructor");  
                System.out.println(" (3) Employee's no-arg constructor is invoked" );  
            }  
  
            public Employee(String s) {  
                System.out.println(s);  
            }  
        }  
  
        class Person {  
            public Person() {  
                System.out.println(" (1) Person's no-arg constructor invoked" );  
            }  
        }  
    }  
}
```

7. Execute println

# Chaining

```
public class Faculty extends Employee {  
    public static void main(String[] args) {  
        new Faculty();  
    }  
  
    public Faculty() {  
        System.out.println(" (4) Faculty's no-arg constructor is invoked" );  
    }  
  
    class Employee extends Person {  
        public Employee() {  
            this(" (2) Invoke Employee's overloaded constructor" );  
            System.out.println(" (3) Employee's no-arg constructor is invoked" );  
        }  
  
        public Employee(String s) {  
            System.out.println(s);  
        }  
    }  
  
    class Person {  
        public Person() {  
            System.out.println(" (1) Person's no-arg constructor invoked" );  
        }  
    }  
}
```

8. Execute println

# Chaining

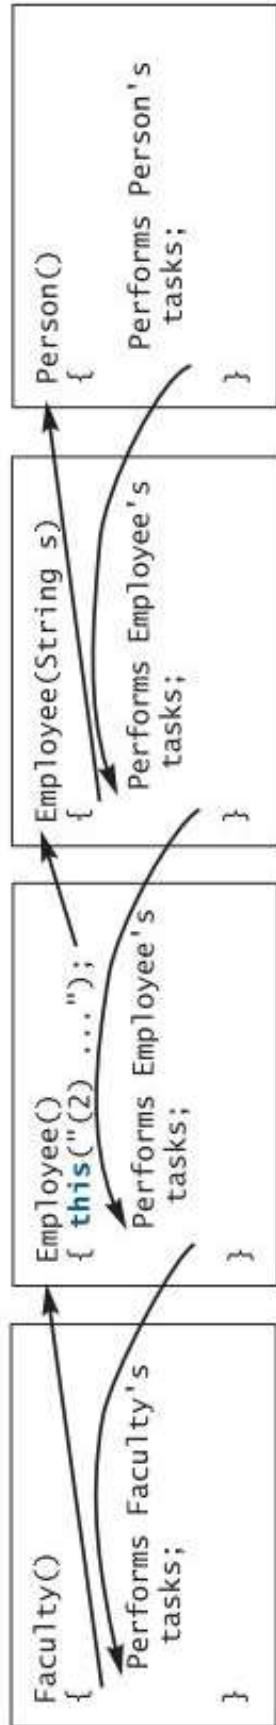

```
public class Faculty extends Employee {  
    public static void main(String[] args) {  
        new Faculty();  
  
        public Faculty() {  
            System.out.println(" (4) Faculty's no-arg constructor is invoked");  
        }  
  
        class Employee extends Person {  
            public Employee() {  
                this(" (2) Invoke Employee's overloaded constructor");  
                System.out.println(" (3) Employee's no-arg constructor is invoked");  
            }  
  
            public Employee(String s) {  
                System.out.println(s);  
            }  
  
            class Person {  
                public Person() {  
                    System.out.println(" (1) Person's no-arg constructor invoked");  
                }  
            }  
        }  
    }  
}
```

9. Execute println

~~System.out.println(" (4) Faculty's no-arg constructor is invoked");~~

# Chaining

- Chaining in the program:

# Chaining

- Find out the errors in the program:

```
public class Apple extends Fruit {  
}  
  
class Fruit {  
    public Fruit(String name) {  
        System.out.println("Fruit's constructor is invoked");  
    }  
}
```

**Subclass/Superclass**

# Subclass

- A subclass extends properties and methods from the superclass.
- You can also:
  - Add new properties
  - Add new methods
  - Override the methods of the superclass

## Subclass

- You could rewrite the printCircle() method in the Circle class as follows:

```
public void printCircle() {  
    System.out.println("The circle is created " +  
        super.getDateCreated() + " and the radius is " + radius);  
}
```

# Overriding

# Overriding

- A subclass inherits methods from a superclass.
- Sometimes it is necessary for the subclass to modify the implementation of a method defined in the superclass.
- This is referred to as *method overriding*.

# Overriding

- Method overriding

```
public class Circle4 extends GeometricObject {
    // Other methods are omitted

    /** Override the toString method defined in GeometricObject */
    public String toString() {
        return super.toString() + "\nradius is " + radius;
    }
}
```

# Overriding

- An instance method can be overridden only if it is accessible.
  - Thus a private method cannot be overridden.
  - If a method defined in a subclass is private in its superclass, the two methods are completely unrelated.

# Overriding

- Like an instance method, a static method can be inherited.
- However, a static method cannot be overridden.
- If a static method defined in the superclass is redefined in a subclass, the method defined in the superclass is hidden.

# Overriding

## • Overriding vs. overloading

```
public class Test {  
    public static void main(String[] args) {  
        A a = new A();  
        a.p(10);  
        a.p(10.0);  
    }  
  
    class B {  
        public void p(double i) {  
            System.out.println(i * 2);  
        }  
    }  
  
    class A extends B {  
        // This method overrides the method in B  
        public void p(double i) {  
            System.out.println(i);  
        }  
    }  
}
```

```
public class Test {  
    public static void main(String[] args) {  
        A a = new A();  
        a.p(10);  
        a.p(10.0);  
    }  
  
    class B {  
        public void p(double i) {  
            System.out.println(i * 2);  
        }  
    }  
  
    class A extends B {  
        // This method overloads the method in B  
        public void p(int i) {  
            System.out.println(i);  
        }  
    }  
}
```

# Object Class

# Object Class

- Every class in Java is descended from the java.lang.Object class.
- If no inheritance is specified when a class is defined, the superclass of the class is Object.

# Object Class

- Equivalent

```
public class ClassName {  
    ...  
}
```

Equivalent

---

```
public class ClassName extends Object {  
    ...  
}
```

# Object Class

- The `toString()` method returns a string representation of the object.
- The default implementation returns a string consisting of:
  - a class name of which the object is an instance,
  - `(@)`,
  - and a number representing this object.

# Object Class

```
Loan loan = new Loan();
System.out.println(loan.toString());
```

- The code displays something like **Loan@15037e5**.
- This message is not very helpful or informative.
- Usually you should override the toString method so that it returns a digestible string representation of the object.

# Polymorphism

# Polymorphism

- An object of a subtype can be used wherever its supertype value is required.
- This feature is known as *polymorphism*.

# Polymorphism

- Three pillars of OOP
  - 1. Encapsulation
  - 2. Inheritance
  - 3. Polymorphism

## • Polymorphism

```
public class PolymorphismDemo {  
    /** Main method */  
    public static void main(String[] args) {  
        // Display circle and rectangle properties  
        displayObject(new Circle(1, "red", false));  
        displayObject(new Rectangle(1, 1, "black", true));  
    }  
  
    /** Display geometric object properties */  
    public static void displayObject(GeometricObject1 object) {  
        System.out.println("Created on " + object.getDateCreated() +  
                           ". Color is " + object.getColor());  
    }  
}
```

## Code

# Code

- If polymorphism is used:
  - Which implementation is used will be determined dynamically by the Java Virtual Machine at runtime.
  - This capability is known as *dynamic binding*.

# Code

```
public class DynamicBindingDemo {  
    public static void main(String[] args) {  
        m(new GraduateStudent());  
        m(new Student());  
        m(new Person());  
        m(new Object());  
    }  
  
    public static void m(Object x) {  
        System.out.println(x.toString());  
    }  
  
    class GraduateStudent extends Student {  
    }  
  
    class Student extends Person {  
        public String toString() {  
            return "Student";  
        }  
    }  
  
    class Person extends Object {  
        public String toString() {  
            return "Person";  
        }  
    }  
}
```

# Binding

- Suppose an object  $o$  is an instance of classes  $C_1, C_2, \dots, C_{n-1}$ , and  $C_n$ , where  $C_1$  is a subclass of  $C_2$ ,  $C_2$  is a subclass of  $C_3, \dots$ , and  $C_{n-1}$  is a subclass of  $C_n$ .
- That is,  $C_n$  is the most general class, and  $C_1$  is the most specific class.
  - In Java,  $C_n$  is the Object class.

# Binding

- If  $o$  invokes a method  $p$ , the JVM searches the implementation for the method  $p$  in  $C_1$ ,  $C_2, \dots, C_{n-1}$  and  $C_n$ , in this order, until it is found.
- Once an implementation is found, the search stops and the first-found implementation is invoked.

If  $o$  is an instance of  $C_1$ ,  $o$  is also an instance of  $C_2, C_3, \dots, C_{n-1}$ , and  $C_n$

# Binding

- Matching a method signature
  - The compiler finds a matching method according to parameter type, number of parameters, and order of the parameters at compilation time.
- Binding a method
  - A method may be implemented in several subclasses.
  - The Java Virtual Machine dynamically binds the implementation of the method at runtime.

## Generic Programming

- Polymorphism allows methods to be used generically for a wide range of object arguments.
- This is known as generic programming.

# Binding

- If a method's parameter type is a superclass (e.g., Object), you may pass an object to this method of any of the parameter's subclasses (e.g., Student or String).
- When an object (e.g., a Student object or a String object) is used in the method, the particular implementation of the method of the object that is invoked (e.g., `toString`) is determined dynamically.

Casting

# Casting

- Casting can be used to convert an object of one class type to another within an inheritance hierarchy.

```
Object o = new Student(); // Implicit casting  
m(o);
```

```
Student b = (Student)o; // Explicit casting
```

# Casting

- The following statement causes a compilation error:

```
Student b = o;
```

- Because a Student object is always an instance of Object, but an Object is not necessarily an instance of Student!

```
Student b = (Student)o; // Explicit casting
```

# Casting

- Explicit casting must be used when casting an object from a superclass to a subclass.
  - This type of casting may not always succeed.

# instanceof

- Use the `instanceof` operator to test whether an object is an instance of a class.

```
Object myObject = new Circle();
...
... // Some lines of code
```

```
/* Perform casting if myObject is an instance of Circle */
if (myObject instanceof Circle) {
    System.out.println("The circle diameter is " +
        ((Circle)myObject).getDiameter());
}
...
```

## Code

- This example creates two geometric objects: a circle, and a rectangle. It displays the area and diameter if the object is a circle, and displays area if the object is a rectangle.

Run

TestPolymorphismCasting

Equality

## equals()

- The **equals()** method compares the contents of two objects.
- The default implementation of the equals method in the Object class is as follows

```
public boolean equals(Object obj) {  
    return (this == obj);  
}
```

## equals()

- You can override **equals()** method in your class

```
public boolean equals(Object o) {  
    if (o instanceof Circle) {  
        return radius == ((Circle)o).radius;  
    }  
}
```

ArrayList

# ArrayList

- Array's size is fixed once the array is created.
- Java provides the ArrayList class that can be used to store an unlimited number of objects.

# ArrayList

- **ArrayList**

## java.util.ArrayList

|                                      |   |
|--------------------------------------|---|
| +ArrayList()                         | Creates an empty list.  |
| +add(o: Object) : void               | Appends a new element o at the end of this list.              |
| +add(index: int, o: Object) : void   | Adds a new element o at the specified index in this list.     |
| +clear(): void                       | Removes all the elements from this list.                      |
| +contains(o: Object): boolean        | Returns true if this list contains the element o.             |
| +get(index: int) : Object            | Returns the element from this list at the specified index.    |
| +indexOf(o: Object) : int            | Returns the index of the first matching element in this list. |
| +isEmpty(): boolean                  | Returns true if this list contains no elements.               |
| +lastIndexOf(o: Object) : int        | Returns the index of the last matching element in this list.  |
| +remove(o: Object): boolean          | Removes the element o from this list.                         |
| +size(): int                         | Returns the number of elements in this list.                  |
| +remove(index: int) : Object         | Removes the element at the specified index.                   |
| +set(index: int, o: Object) : Object | Sets the element at the specified index.                      |

Creates an empty list.

Appends a new element o at the end of this list.

Adds a new element o at the specified index in this list.

Removes all the elements from this list.

Returns true if this list contains the element o.

Returns the element from this list at the specified index.

Returns the index of the first matching element in this list.

Returns true if this list contains no elements.

Returns the index of the last matching element in this list.

Removes the element o from this list.

Returns the number of elements in this list.

Removes the element at the specified index.

Sets the element at the specified index.

# Program

- ArrayList
- You will get a compilation warning “unchecked operation.” Ignore it. This warning can be fixed using generic types in Chapter 20.

Run

TestArrayList

# Program

- **MyStack**

## MyStack

-list: ArrayList

+isEmpty(): boolean

+getSize(): int

+peek(): Object

+pop(): Object

+push(o: Object): void

+search(o: Object): int

A list to store elements.

Returns true if this stack is empty.

Returns the number of elements in this stack.

Returns the top element in this stack.

Returns and removes the top element in this stack.

Adds a new element to the top of this stack.

Returns the position of the first element in the stack from the top that matches the specified element.

# Accessibility

# **protected**

- Another visibility modifier
- A protected data or a protected method in a public class can be accessed by any class in the same package or its subclasses
  - Even if the subclasses are in a different package.

Visibility increases

private, none (if no modifier is used), protected, public

# Accessibility

- Accessibility summary

| Modifier  | Accessed on members in a class | Accessed from the same class | Accessed from the same package | Accessed from a subclass | Accessed from a different package |
|-----------|--------------------------------|------------------------------|--------------------------------|--------------------------|-----------------------------------|
| public    | ✓                              | ✓                            | ✓                              | ✓                        | —                                 |
| protected | ✓                              | ✓                            | ✓                              | ✓                        | —                                 |
| default   | ✓                              | ✓                            | ✓                              | —                        | —                                 |
| private   | ✓                              | ✓                            | —                              | —                        | —                                 |

# Accessibility

- Accessibility example

```
package p1;
```

```
public class C1 {  
    public int x;  
    protected int y;  
    int z;  
    private int u;  
  
    protected void m() {  
    }  
}
```

```
public class C2 {  
    C1 o = new C1();  
    can access o.x;  
    can access o.y;  
    can access o.z;  
    cannot access o.u;  
  
    can invoke o.m();  
}
```

```
public class C3 extends C1 {  
    can access x;  
    can access y;  
    can access z;  
    cannot access u;  
  
    can invoke m();  
}
```

```
public class C4 extends C1 {  
    can access x;  
    can access y;  
    cannot access z;  
    cannot access u;  
  
    can invoke m();  
}
```

```
public class C5 {  
    C1 o = new C1();  
    can access o.x;  
    cannot access o.y;  
    cannot access o.z;  
    cannot access o.u;  
  
    cannot invoke o.m();  
}
```

# Accessibility

- A subclass may override a protected method in its superclass and change its visibility to public.
- However, a subclass cannot weaken the accessibility of a method defined in the superclass.
- For example, if a method is defined as public in the superclass, it must be defined as public in the subclass.

**final keyword**

# final

- A **final** class cannot be extended

```
public final class C {  
    // Data fields, constructors, and methods omitted  
}
```

- A **final** variable is a constant

- A **final** method cannot be overridden by its subclasses.

```
public class Test {  
    // Data fields, constructors, and methods omitted  
  
    public final void m() {  
        // Do something  
    }  
}
```
